Keywords: AI adoption barriers | generative AI | innovation resistance | tourism technology | travel planning

ABSTRACT

Many travelers remain hesitant to rely on generative AI for travel planning, despite its growing presence in tourism services. While most existing studies emphasize adoption, this study shifts attention to the relatively underexplored issue of resistance. Drawing on Innovation Resistance Theory (IRT) and qualitative data from a developing country, we identify five core barriers to AI-generated travel advice: usage, value, risk, image, and tradition. We propose a typology of traveler resistance comprising rejecters, postponers, and opinion leaders, each defined by distinct motivations, levels of engagement, and patterns of skepticism. Our findings show that resistance is not fixed but shaped by cultural norms, social context, and personal identity. In rethinking resistance as a situated practice rather than a static outcome, the study extends IRT within tourism research and offers practical guidance for designing AI-based travel services that are culturally attuned, trust-oriented, and responsive to the social meanings embedded in travel planning.

1 | Introduction

Generative Artificial Intelligence (GAI) is increasingly integrated into consumer-facing digital services, including health-care, education, and financial planning. In tourism, its adoption has been especially rapid. Tools such as ChatGPT now assist travelers with itinerary design, destination research, and real-time problem solving (Saleh 2025). These systems aggregate data from diverse sources and produce tailored suggestions based on individual preferences (Wong et al. 2023) and offer both efficiency gains and personalization. As platforms adopt GAI to enhance service delivery, its potential to transform how travelers plan and experience trips is widely acknowledged (Duong et al. 2025; Carvalho and Ivanov 2024; Kim et al. 2024). Despite these advances, public adoption remains uneven. Many

travelers remain reluctant to trust AI-generated travel advice. A recent Longwoods International survey found that only 33% of American travelers were willing to use ChatGPT for planning (Kelleher 2023). Similar hesitation has been reported in other markets, especially where digital trust, cultural expectations, and planning practices diverge from Western norms (e.g., Seyfi, Kim, Nazifi, et al. 2025). This resistance challenges assumptions about the inevitability of AI integration and calls for closer examination of the factors shaping user hesitation.

Most existing research emphasizes the advantages of AI in tourism, including improved decision quality, reduced information overload, and enhanced user experience (Gursoy and Cai 2025; Saleh 2025; Kim et al. 2024; Zhu et al. 2024; Stergiou and Nella 2024). However, such work is largely focused on

adopters, drawing on models (e.g., the technology acceptance model, the diffusion of innovations) to explain motivation and usage (Zhu et al. 2024). Studies on non-adoption are fewer and often limited to Western contexts, where cultural conditions and digital literacies differ significantly (Musyaffi et al. 2022). Moreover, many studies lack a consistent theoretical framework to explain resistance, leading to fragmented findings and limited practical insight (Seyfi, Kim, Nazifi, et al. 2025; Seyfi, Kim, Lee, et al. 2025; Huang et al. 2021; Partala and Saari 2015).

This study addresses these gaps by applying Innovation Resistance Theory (IRT) to investigate why travelers in a developing country, specifically Iran, resist the use of generative AI in travel planning. In doing so, this study aims to examine how and why barriers to generative AI in tourism arise, the behavioral responses they trigger, and seeks to develop a typology of resistance across user groups. IRT is distinct from adoption-based models in that it focuses on barriers rather than incentives. It is therefore better suited to explain functional and psychological sources of hesitation. IRT distinguishes between functional barriers (usability, value, risk) and psychological barriers (tradition, image), offering a structured framework for understanding non-use (Huang et al. 2021; Ram and Sheth 1989; Heidenreich and Handrich 2015).

The study makes three contributions. First, it applies IRT to an emerging and underexplored technology in tourism, offering a novel analysis of resistance to AI-generated travel advice. Second, it introduces a typology of resistance and shows how distinct user groups respond to AI tools. Third, it reinterprets psychological barriers by grounding them in cultural identity, social role expectations, and relational trust, which offers a more context-specific reading of resistance in non-Western settings. By tailoring AI strategies to user typologies and addressing specific psychological and functional concerns, tourism stakeholders can design more adaptive, inclusive, and trustworthy systems that accommodate a wider range of user needs and expectations.

The paper is structured as follows. Section 2 reviews prior research on generative AI in travel planning, focusing on adoption, resistance, and barriers to AI-generated travel advice, and introduces the study's theoretical lens. Section 3 outlines the methodology and data collection. Section 4 presents the findings, followed by the discussion in Section 5. Section 6 concludes with the theoretical and practical implications of the study, along with its limitations and directions for future research.

2 | Literature Review and Theoretical Background

2.1 | The Application of Generative AI in Travel Planning

GAI is being adopted across all phases of the travel experience, before, during, and after the trip (Wong et al. 2023). Travel planning has traditionally been time-consuming, requiring travelers to collect and compare information from various sources, including travel agencies, online forums, social media, and

personal networks (Siyamiyan Gorji et al. 2023a, 2023b; Chen et al. 2025; Kim and Hyun 2024). GAI reduces this effort by offering tailored, data-driven recommendations aligned with individual preferences, thereby simplifying planning and reducing associated costs (Wong et al. 2023; Kim et al. 2024).

In the pre-trip phase, GAI can assist with destination selection, route planning, accommodation, transportation, and activity choices (Wong et al. 2023; Duong et al. 2025). When outputs are accurate and relevant, they can reduce information overload and improve planning efficiency (Carvalho and Ivanov 2024; Stergiou and Nella 2024). During the trip, AI-powered tools suggest itinerary updates, assist with content creation for social media, and offer translation support (Gupta et al. 2024; Carvalho and Ivanov 2024; Wong et al. 2023). These functions help address communication barriers and increase engagement. GAI can also provide historical and cultural context at tourist sites, supporting user learning (Duong et al. 2025). After travel, GAI tools enable users to reflect on and share their experiences by generating reviews and feedback, thereby supporting community contributions and platform interaction (Wong et al. 2023). Integration with booking platforms, service directories, and review systems links informational and transactional elements of tourism into a continuous user experience (Dwivedi et al. 2024; Gursoy 2025; Kim et al. 2024).

However, despite these benefits, several issues limit the broader adoption of GAI in tourism. These include high deployment and maintenance costs, difficulties in updating real-time information, data privacy and cybersecurity concerns, and the lack of emotional responsiveness in AI systems (Gursoy 2025; Christensen et al. 2025; Ali et al. 2023). Users also express discomfort with the perceived dehumanization of travel planning and concerns about AI displacing human labor. Addressing these issues requires not only technical refinement and regulatory measures but also a clearer understanding of user resistance (Huang et al. 2021; Seyfi, Kim, Nazifi, et al. 2025). While the literature has emphasized the functional potential of GAI, it remains largely focused on benefits and adoption (e.g., Zhu et al. 2024). Resistance is relatively overlooked, especially in non-Western settings. Few studies explore how cultural, emotional, and symbolic factors influence travelers' rejection of AI tools. This study addresses these aforementioned gaps by drawing on the theoretical lens of innovation resistance to examine the functional and psychological barriers that shape resistance to GAI in a developing country context.

2.2 | Factors Influencing Emerging Technology's Adoption and Resistance

The adoption of emerging technologies has been studied across fields such as marketing, healthcare, information systems, and tourism. However, much of this research displays a pro-innovation bias by emphasizing adoption drivers while overlooking resistance (e.g., Arora et al. 2014; Venkatesh et al. 2024; Heidenreich and Handrich 2015; Kautish et al. 2023; Laukkanen 2016; Kaur et al. 2020). This tendency is particularly evident in tourism research, where the focus has remained on efficiency, personalization, and user experience, with limited attention to user hesitation (Seyfi, Kim, Nazifi, et al. 2025; Seyfi,

TABLE 1 | Factors shaping tourist AI adoption and resistance.

Level	Definition	Key factors
Individual level	Personal traits and skills affecting AI usage	Self-efficacy, personal innovativeness, ICT/AI knowledge, prior system use, self-image, readiness to learn
Social level	External influences and societal expectations	Perceptions of AI in one's social environment, social image, perceived community impact
Cognitive/emotional level	Psychological and affective responses to AI	Technology anxiety, perceived risks, resistance to change, trust, perceived safety

Sources: Arora et al. (2014); Venkatesh et al. (2024); Heidenreich and Handrich (2015); Kautish et al. (2023); Laukkanen (2016); Kaur et al. (2020); Seyfi, Kim, Nazifi, et al. (2025); Seyfi, Kim, Lee, et al. (2025); Ram and Sheth (1989); Huang et al. (2021).

Kim, Lee, et al. 2025). Yet resistance is a common consumer reaction to innovation, especially when adoption requires behavioral change or disrupts existing routines (Ram and Sheth 1989; Huang et al. 2021). Even when new technologies offer clear benefits, resistance often remains. This helps explain why many innovations fail, with long-standing estimates placing failure rates between 50% and 90% (Heidenreich and Spieth 2013). Rogers (2003) categorizes late adopters as “laggards,” noting that resistance tends to rise with perceived disruption. Laukkanen et al. (2008) further argue that resistance must be addressed directly, as it can delay or block adoption altogether.

Factors influencing resistance to AI can be grouped into three levels: individual, social, and cognitive/emotional, as summarized in Table 1. At the individual level, traits including self-efficacy, personal innovativeness, readiness to learn, prior experience, and general attitudes toward technology are all relevant (Khanfar et al. 2025). Psychological barriers, particularly technology anxiety, often lower confidence and reduce willingness to engage with AI-based tools (Zhu et al. 2025). Familiarity with AI applications also shapes perceptions of usefulness and usability (Christensen et al. 2025). Social factors influence resistance as well. Individuals are not isolated decision-makers; social influence, perceived norms, and concern for one's image play a role in adoption decisions. Social pressures, expectations, and the fear of negative evaluation can discourage engagement with AI tools (Khanfar et al. 2025). Broader societal concerns, such as AI's perceived threat to communal values or social traditions, also contribute to resistance, particularly when AI disrupts established practices (Vichitkraivin and Naenna 2021). Cultural context further shapes resistance. Differences in digital infrastructure, attitudes toward innovation, and prevailing values all affect how users respond to generative AI. Users from different cultural settings may prioritize different technological features and evaluate innovations according to local norms (Chandra and Kumar 2018; Kumar et al. 2022).

Trust also plays a central role. Users often remain skeptical of AI-generated advice, especially in high-stakes scenarios such as booking travel or accommodations (Dwivedi et al. 2024; Ali et al. 2023; Seyfi, Kim, Nazifi, et al. 2025). Ongoing concerns about misinformation, data accuracy, and algorithmic bias undermine confidence in AI systems (Carvalho and Ivanov 2024; Kim et al. 2025; Christensen et al. 2025). Trust is both cognitive and emotional. Mcknight et al. (2011) distinguish between interpersonal and system-based trust, emphasizing reliability, security, and functionality as key components (Kim et al. 2025).

2.3 | Barriers to the Adoption of AI-Generated Travel Advice

Despite its increasing presence in tourism, the adoption of generative AI remains limited and uneven. While most existing research is still conceptual, it identifies a range of interconnected barriers that limit acceptance. These reflect individual constraints as well as broader concerns about AI-driven interactions. Drawing on existing literature, these barriers can be grouped into seven categories, as summarized in Table 2. Functional and usability issues are among the most frequently cited. Travelers often struggle with AI interfaces, encounter unreliable outputs, or face communication failures when systems do not ask clarifying questions (Carvalho and Ivanov 2024). Misinformation and AI “hallucinations”, fabricated content presented as fact, further undermine trust. When such errors affect key decisions, such as accommodation or safety, skepticism increases (Christensen et al. 2025; Kim et al. 2025). Psychological barriers are also important. Technology anxiety, fear of losing control, and general discomfort with automation reduce users' willingness to engage with AI. Even those who recognize its benefits may resist due to emotional unease or unfamiliarity (Duong et al. 2025). AI's inability to respond to emotional cues can also create a sense of isolation, particularly for travelers who view planning as a social or affective activity (Neuhofer 2025).

Social and cultural factors further complicate adoption. AI is often perceived as impersonal, which diminishes the perceived value of the planning process. For many, travel planning is not just functional but also social. Cultural and linguistic biases embedded in AI tools may lead to irrelevant or exclusionary recommendations, reinforcing a sense of unfairness (Chandra and Kumar 2018; Kumar et al. 2022). Ethical concerns also contribute to resistance. GAI models can replicate social biases, offering advice that reflects stereotypes or exclusionary patterns. Zhuo et al. (2023) identify four core ethical risks in tourism AI: bias, reliability, robustness, and toxicity. These are particularly relevant in a field where decisions are highly personal and culturally sensitive. Economic and technical limitations matter as well. Some users perceive AI tools as expensive or unnecessary. Others lack the digital skills needed to use them effectively, especially in settings with limited infrastructure or digital literacy (Goel et al. 2022). Financial constraints can further reduce adoption, particularly where tourism itself is considered a luxury. Security and privacy concerns remain strong deterrents. Earlier studies on mobile travel platforms found that data privacy fears discouraged booking (Luo et al. 2010). Similar concerns apply to

TABLE 2 | Key barriers to Generative AI adoption in tourism.

Dimension	Description	Key factors
Psychological barriers	Emotional and cognitive resistance to adopting AI in travel planning	Technology anxiety, lack of trust, resistance to change, feelings of loneliness and alienation
Social barriers	Impact of cultural expectations, social norms, and need for human interaction	Impersonal nature of AI, reduced social value, cultural and linguistic bias, traditional norms
Functional/technical barriers	Usability, reliability, and performance limitations of AI systems	Interface challenges, misinformation, lack of clarification, user error, low technical proficiency
Ethical barriers	Moral concerns about fairness, inclusivity, and accountability	Biased outputs, unreliable responses, harmful content
Financial barriers	Perceptions of cost and doubts about value	High perceived cost, uncertainty about benefits
Security and privacy barriers	Concerns about data misuse, surveillance, and breaches	Privacy risks, data security concerns
Information barriers	Limited knowledge about AI tools and their capabilities	Low awareness, insufficient guidance, dependence on traditional information sources

Sources: Carvalho and Ivanov (2024); Christensen et al. (2025); Kim et al. (2025); Duong et al. (2025); Neuhofer (2025).

GAI, which often requires users to share sensitive personal data (Kim et al. 2025). Finally, limited awareness and familiarity with GAI technologies contribute to underuse. Many travelers do not fully understand what these systems can do or how to use them, leading to continued reliance on traditional planning sources even when AI tools are available.

2.4 | Explaining Non-Adoption of Generative AI Through the Theoretical Lens of Innovation Resistance

IRT introduced by Ram (1987) and further developed by Ram and Sheth (1989), offers a structured framework for understanding why individuals resist adopting new technologies, even when those technologies offer clear advantages (Huang et al. 2021; Baklouti and Boukamcha 2024). Unlike adoption-centered models (e.g., technology acceptance model or diffusion of innovations) which emphasize motivation, ease of use, or innovation characteristics that encourage uptake (Zhu et al. 2024), IRT adopts a barrier-oriented lens and is specifically designed to explain non-adoption or active opposition, rather than the factors that facilitate acceptance (Ram and Sheth 1989; Huang et al. 2021; Seyfi, Kim, Nazifi, et al. 2025).

IRT identifies resistance as a response to innovations that disrupt an established and satisfactory status quo or conflict with existing beliefs, norms, or routines (Huang et al. 2021). Functional barriers relate to the technology itself, such as perceived effort, unclear benefits, or various types of risk (economic, performance, or social). Psychological barriers refer to the innovation's contradiction with identity, culture, or social roles. Tradition barriers demonstrate discomfort with altering ingrained habits, while image barriers concern how the use of an innovation may be perceived socially (Kaur et al. 2020; Baklouti and Boukamcha 2024). Resistance is not uniform. IRT distinguishes between active and passive resistance (Heidenreich and Handrich 2015). Active forms are linked to negative judgments

about the innovation's function, while passive forms are driven by discomfort or ambivalence, often rooted in identity or social positioning. Scholars distinguish between individual and social forms of resistance, which span a spectrum from private hesitation to active opposition. While some users delay engagement without outright rejection, others influence public sentiment and discourage adoption more visibly (Heidenreich and Spieth 2013; Talwar et al. 2020).

IRT is particularly well-suited to this study for three reasons. First, the aim of this research is not to measure user intention or likelihood to adopt generative AI, but to examine why users resist it, often consciously and persistently. Adoption-centered models such as the technology acceptance model or diffusion of innovations provide limited explanatory power for negative, ambivalent, or socially embedded forms of resistance that are not based on rational evaluation alone. Second, IRT allows for a distinction between functional barriers, such as low perceived value, usability concerns, and perceived risks, and psychological barriers, including tradition and image concerns (Ram and Sheth 1989; Heidenreich and Handrich 2015). This distinction aligns closely with the approach and aim of this study, which seeks to explore how both technical and symbolic concerns shape user resistance.

3 | Methodology

3.1 | Research Design and Data Collection

This study uses a qualitative approach to explore how travelers resist AI-generated travel advice. This method is suitable for understanding personal views, especially in areas that are not well studied and where context matters (Lim 2024). It helps show how people make sense of, judge, and react to AI tools in their social and cultural settings. By focusing on participants' own accounts, the study uncovers personal, emotional, and situational factors that shape resistance to generative AI in tourism. The research

was conducted in Iran, a developing country with a large and active outbound tourism market; over 14 million international departures were recorded annually before recent economic and geopolitical disruptions (Farhikhtegan Daily 2024). The country has a relatively high rate of internet users, 85% (Dataak 2024), with over 66 million smart mobile devices in use (Asriran 2023), and growing digital platform usage, including Instagram with over 33 million active users, Telegram with 26 million, and WhatsApp with 22 million users (Dataak 2024; ISPA 2024). However, Iran also faces infrastructural constraints, intermittent access to global services, and limited public trust in automated systems (Siyamiyan Gorji et al. 2023a, 2023b). AI literacy remains uneven, with higher awareness among younger, urban populations and more cautious engagement among older or less digitally connected groups (ISPA 2024). According to a recent study, only 46% of social media users in Iran are women, while 54% are men (ISPA 2024). Recent findings from LifeWeb (2024) also provide additional insights into the landscape of social media and AI-related content in Iran. Analysis of Persian-language content on platforms such as X (Twitter), Telegram, and Instagram shows that more than 25% of AI-related posts focus on educational aspects of the technology. Specifically, 37% of AI-related content on Instagram is technical and educational in nature; this proportion is 23% on Telegram and 15% on X (Twitter). In terms of AI tools, ChatGPT leads with a 60% share of related content, followed by Gemini (15%), Copilot (10%), MidJourney (7%), and Claude.ai (3%).

Purposive sampling was used to recruit outbound travelers who had taken at least four international trips in the past 3 years. This criterion ensured that participants were actively engaged in travel planning and had likely encountered AI-generated recommendations. Purposive sampling is appropriate for exploratory qualitative research where the goal is depth rather than representativeness (Ahmad and Wilkins 2024). Targeting experienced travelers increased the likelihood of obtaining reflective and informed perspectives on AI use. Participants were recruited through two channels: (1) three outbound-focused travel agencies that provided access to regular clients, and (2) public Instagram accounts that featured user-generated travel content. All participants were screened using consistent inclusion criteria. Each participant was contacted individually, briefed on the study's purpose, and invited to take part in a semi-structured interview conducted online. To broaden the sample, snowball sampling was also used; participants were invited to refer others who met the same criteria. This approach was appropriate given the peer-driven nature of travel decision-making and the role of social influence in shaping views on AI (Saunders et al. 2018). Although efforts were made to ensure diversity across gender, age, and location, the sample reflects more digitally engaged and travel-experienced individuals. We acknowledge this as a limitation and note that occasional or digitally less fluent travelers may hold different views.

The semi-structured interview guide was developed through a review of prior research on technology resistance, AI adoption, and consumer behavior in tourism and other related fields. The questions were shaped by IRT as used in broader studies (e.g., Ram and Sheth 1989; Huang et al. 2021; Heidenreich and Handrich 2015), its application in tourism (e.g., Seyfi, Kim, Nazifi, et al. 2025; Seyfi, Kim, Lee, et al. 2025), and recent

work on generative AI in tourism (e.g., Duong et al. 2025; Carvalho and Ivanov 2024; Kim et al. 2024; Gursay and Cai 2025; Saleh 2025; Zhu et al. 2024; Stergiou and Nella 2024). Additional inspiration was drawn from studies exploring digital resistance in service contexts (Kaur et al. 2020; Talwar et al. 2020; Musyaffi et al. 2022). To ensure conceptual alignment, questions were designed to explore issues related to usability, value, risk, image, and tradition, core constructs in IRT. The guide consisted of open-ended questions that encouraged participants to describe their travel planning behaviors, experiences with generative AI tools, and reasons for adoption or avoidance. Probing questions were used to explore specific perceptions of trust, usefulness, cultural fit, and personal identity in relation to AI-generated advice. The structure followed best practices in qualitative research to promote reflexive and context-rich responses (Creswell and Poth 2018). The interview guide was piloted with four participants to ensure clarity and relevance. Minor adjustments were made based on their feedback, particularly to improve phrasing and cultural sensitivity (Siyamiyan Gorji et al. 2023a, 2023b). These pilot interviews were not included in the final analysis but helped refine the instrument's validity and flow. Informed consent was obtained verbally at the start of each session. Data collection continued until theoretical saturation was reached after 22 interviews (see Table 3 for the profile of interviewees). This number aligns with qualitative research norms where the focus is on meaning and thematic depth rather than statistical coverage (Czernek-Marszałek and McCabe 2024).

3.2 | Data Analysis

The data analysis followed the thematic approach proposed by Gioia et al. (2013), which emphasizes grounded theory development through systematic concept formation. This method was used to identify patterns, themes, and theoretical constructs emerging from the interview data and to ensure a link between empirical evidence and theoretical interpretation. The analysis began with immersion through repeated readings of all interview transcripts. The two lead member of the research team, fluent in Persian, independently conducted open coding using the participants' own words. This inductive phase involved identifying key phrases and expressions that reflected how participants made sense of AI-generated travel advice. These initial codes were not guided by pre-existing categories but emerged directly from the data (Nowell et al. 2017). The codes were entered into a shared spreadsheet and cross-compared. Verbatim extracts and associated codes were then grouped into first-order concepts, which closely represented participants' language and perspectives. These concepts reflected discrete attitudes, behaviors, or concerns (e.g., "AI can't understand emotions," "I prefer asking real people"). The team then collaboratively analyzed these first-order concepts to develop second-order themes, more abstract, theoretical categories that synthesized commonalities across interviews (e.g., "loss of autonomy," "contextual mistrust"). Once second-order themes were finalized, they were organized into aggregate dimensions, which demonstrated higher-order patterns in the data. These dimensions were then mapped onto the two overarching categories from IRT: functional and psychological barriers (Ram and Sheth 1989; Heidenreich and Handrich 2015). This final step allowed for

TABLE 3 | Profile of interview participants.

Participant ID	Gender	Age	Number of outbound trips (last 3 years)
P1	Male	35–40	6
P2	Female	28–33	4
P3	Male	55–60	5
P4	Female	30–35	7
P5	Male	40–45	5
P6	Female	50–55	4
P7	Male	25–30	4
P8	Female	63–70	6
P9	Male	37–42	5
P10	Female	29–34	7
P11	Male	41–46	6
P12	Female	27–32	4
P13	Male	48–53	8
P14	Female	31–36	5
P15	Male	39–44	7
P16	Female	46–51	6
P17	Male	36–41	4
P18	Female	32–37	6
P19	Male	38–43	5
P20	Female	30–35	5
P21	Male	47–52	7
P22	Female	28–33	4

theoretical structuring without compromising the grounded nature of the analysis. In line with the aims of the study, a spectrum of resistance across user groups was also developed by comparing how different participants engaged with or distanced themselves from AI tools. This comparison revealed varied positions along a continuum, from hesitant users to vocal rejecters, which informed the typology presented in the findings.

4 | Findings

The findings show that travelers' resistance to using generative AI for travel planning is shaped by a combination of functional and psychological barriers. These themes are summarized in the thematic structure presented in Figure 1. While some participants were younger and more familiar with technology, others expressed more traditional attitudes and greater skepticism toward digital tools. This variation highlights the role of both individual predispositions and broader socio-cultural factors in shaping resistance. In addition to identifying specific barriers, the analysis revealed three overarching types of resistance among travelers. These types reflect distinct patterns in how individuals respond to AI-generated travel advice, based on their attitudes, experiences, and willingness to engage with the technology.

4.1 | Functional Barriers

Functional barriers refer to practical obstacles (Huang et al. 2021) that may limit the effective use of generative AI in travel planning. These barriers relate to usability issues, low perceived value, and concerns about various forms of risk. For many participants, such challenges reduced the perceived usefulness of AI tools, often resulting in frustration or disengagement. The analysis identified three main types of functional barriers: usage, value, and risk.

FIGURE 1 | Factors affecting resistance to AI-generated travel advice.

4.1.1 | Usage Barriers

Usage barriers emerge when users find AI systems difficult to use due to technical limitations, low digital literacy, or a mismatch between system functionalities and user expectations (Kaur et al. 2020). Several participants reported that infrastructural constraints, such as limited internet access during travel, make AI tools unreliable. As Participant 2 explained:

The internet doesn't always work, especially in faraway or poorer areas, or when you're travelling. If you rely only on AI to plan your trip, it might not help much when the connection is bad.

In addition to infrastructure, some participants struggled with the interface and conversational logic of ChatGPT. Participant 8 noted:

I'm not very good with technology, so using ChatGPT wasn't simple for me. It's not just about asking questions, you also have to know how to ask them the right way. I tried asking about flights, but since it couldn't book them, I had to use a different website. That made the whole process feel disconnected.

Participants also expressed dissatisfaction with ChatGPT's ability to manage complex queries. Participant 12 stated:

When I try to plan a detailed trip with stops in different cities and different ways of getting around, ChatGPT often doesn't give a full answer. I'm not sure if I'm asking the wrong way or if it's just something AI can't do well.

Another frequently cited limitation was the lack of visual information. Participant 7 emphasized the importance of visual aids in the travel planning process:

ChatGPT only works with text, so it doesn't show maps, pictures, or videos. But as you know, those things help a lot when you're trying to understand travel details or choose where to go.

Finally, issues related to language interpretation and contextual understanding were also raised. Participant 14 observed:

ChatGPT is good with words, but sometimes it doesn't quite get what I'm trying to say. That can cause confusion or give me the wrong information.

4.1.2 | Value Barriers

Value barriers arise when users fail to perceive clear advantages of a new technology over existing alternatives (Ram and Sheth 1989; Huang et al. 2021; Baklouti and Boukamcha 2024). In the context of generative AI, this includes doubts about cost-effectiveness, relevance, and the overall benefit compared to

familiar tools and human input (Seyfi, Kim, Nazifi, et al. 2025; Seyfi, Kim, Lee, et al. 2025). Across interviews, participants repeatedly questioned whether ChatGPT added any meaningful value to their travel planning routines. Several participants compared ChatGPT unfavorably with established platforms. Participant 13 remarked:

I already use [Booking.com](#) for hotels and flights. Why use ChatGPT when it doesn't show reviews, prices, or photos?

Human recommendations were also seen as more trustworthy and relevant. Participant 4 stated:

I trust friends and family who've travelled before because their advice feels more personal and dependable. ChatGPT is okay for general info, but when it comes to something as important as my vacation, I'd rather hear from real people.

Many users viewed AI-generated content as too general or disconnected from real-world experience. Participant 6 echoed this view:

TripAdvisor, Reddit, and travel blogs are more helpful because the advice comes from people who've actually been there. Why trust ChatGPT when it doesn't even say where its suggestions come from?

ChatGPT's inability to handle complete travel logistics was seen as a critical weakness. As Participant 16 explained:

When I went to Europe, a travel agency took care of everything for me, flights, hotels, visas, and even local tour guides. ChatGPT can suggest ideas, but it can't book anything or handle the details, so it's not nearly as useful.

Others questioned the usefulness of the paid version, especially when free tools were seen as more reliable. Participant 16 commented:

.... I didn't think it was worth it...The answers often felt repetitive, and sometimes they were wrong. The paid version costs money, but a quick Google search gave me better info without needing to check it all over again.

Beyond functionality, the impersonal nature of AI-generated advice further contributed to the perception of low value. Participant 1 explained:

AI is okay for general ideas, but it's not good with the details. It lacks the human touch that makes travel advice helpful. Most of the time, it just gives generic top 10 lists you can find anywhere online, that doesn't feel like real advice.

4.1.3 | Risk Barriers

Risk barriers refer to concerns about misinformation, data accuracy, privacy, and financial security that hinder the adoption of generative AI in travel planning (Ram and Sheth 1989; Huang et al. 2021; Baklouti and Boukamcha 2024). In this study, participants expressed consistent skepticism about the reliability of AI-generated travel recommendations, particularly when decisions involve cost, safety, or time-sensitive details. One common concern was inaccurate or misleading content, which undermined trust. Participant 9 shared:

I asked ChatGPT for family-friendly hotels in Antalya, but it suggested places that were either too expensive or not really right for kids. I can't take that kind of risk when planning a trip.

Participants also highlighted the issue of AI hallucinations where the system produces plausible but false or unverifiable information (Christensen et al. 2025). Participant 12 described a concerning incident:

.... It always gives the same generic list of places to visit, eat, or stay. But two of the places it suggested didn't even exist. Imagine being in a foreign country, relying on that info, and then finding out it's wrong. That would be a nightmare.

This fear of misinformation in unfamiliar environments was shared by others. Participant 13 noted:

...there's no real guarantee that AI will fix our travel problems or make things easier...it could just make things more frustrating.

Participant 10 also added:

...I tested it by asking for nearby UNESCO sites, and it messed up...It got several wrong, even though that's basic info you can easily find online...If it can't get that right, how can I trust anything else it suggests?

Several participants also pointed to outdated information as a significant limitation. As Participant 15 explained:

... Its info isn't up to date, so I don't trust it for important travel stuff, like border or visa rules. Those things change often, and getting them wrong can ruin a trip.

Participant 17 raised a related issue:

... Other than listing the usual things to do and places to see, I'm not sure how accurate ChatGPT is with things that change, like opening hours. The biggest difference from a search engine is that you can't see

where its info comes from, so it's hard to know if you can trust it.

4.2 | Psychological Barriers

Psychological barriers refer to internal resistance shaped by personal beliefs, values, habits, and cultural norms. These barriers are less about the functional limitations of technology and more about its perceived threat to identity, autonomy, and established routines (Ram and Sheth 1989; Huang et al. 2021). In this study, two forms of psychological resistance were most evident: image barriers and tradition barriers.

4.2.1 | Image Barriers

Image barriers arise when an innovation challenges how users see themselves or wish to be perceived by others (Ram and Sheth 1989). Several participants framed trip planning as a personal skill or point of pride, and perceived AI tools as undermining that identity. Participant 5 stated:

I've been travelling for years, and I enjoy planning my own trips. I like choosing the places, the things to do, and handling the details myself. Using ChatGPT feels like handing that over to a machine, and it takes away the personal part I care about. It just feels less meaningful.

This resistance is tied to a perceived loss of competence or control. For some, using generative AI felt like relinquishing a valued part of the travel experience. Participant 15 echoed this sentiment:

...planning trips is a big part of who I am. If I use ChatGPT, it feels like I'm giving up something I enjoy and take pride in, like I'm losing part of what makes the trip feel mine.

Participant 19 also explained:

...ChatGPT gives broad suggestions, but they're not really based on what I'm looking for...It doesn't take into account my budget, how I like to travel, or the kind of experience I want. So even if the ideas sound fine, they feel very general, like they could be for anyone... I think it doesn't feel like it understands me or what would make the trip feel right.

4.2.2 | Tradition Barriers

Tradition barriers arise when new technologies conflict with long-standing cultural practices, habits, and social norms (Ram and Sheth 1989; Huang et al. 2021; Kaur et al. 2020). In this study, many participants resisted generative AI because it disrupted the interpersonal and culturally embedded aspects

of trip planning. A recurring theme was the preference for personal recommendations over algorithmic suggestions. Participant 16 stated:

... In our culture, we usually turn to people we know for advice. There's a kind of trust that comes from hearing from friends or family who've been there. AI feels too cold and impersonal, it doesn't really give that same sense of trust or connection... you know what I mean.

Several participants described a habitual reliance on travel agencies and face-to-face planning. Participant 18 shared:

I still prefer going to a travel agency and talking to someone face to face, that's how I've always planned my trips. It feels more real and reassuring than using a screen or a chatbot.

Here, resistance is not necessarily about the limitations of AI but about the perceived loss of a familiar and valued routine. For some, planning is not simply functional but also a social ritual. Trip planning was also described as a collaborative family activity, where shared decision-making reinforces bonds. Participant 21 explained:

In my family, we plan trips together. We talk about everything, where to go, what to do, how to make it work for everyone. It's part of the fun and brings us closer... I've always said this using ChatGPT takes that away. It turns planning into something you do alone, and it feels isolating. There's no shared excitement, just me and a screen. That's not how we do it, and it just doesn't feel the same.

4.3 | Typology of Resistance

The findings reveal three overarching types of resistance to generative AI among travelers: rejecters, postponers, and opinion leaders. These categories are not mutually exclusive. While most participants aligned predominantly with one type, several described hybrid positions or shifting attitudes depending on the context, personal experience, or specific encounters with AI. This typology reflects not only behavioral tendencies but also the underlying beliefs, identity concerns, and cultural expectations that shape resistance to automated travel planning. Overall, these resistance types illustrate a spectrum of responses to generative AI in travel planning.

4.3.1 | Rejecters

Rejecters show clear disengagement from AI-generated travel advice, often without actively opposing it. Their resistance is largely passive but grounded in strong perceptions of risk, particularly functional and social. They question the reliability and accuracy of AI tools, but their skepticism extends beyond performance to include deeper discomfort with automation in a culturally and

emotionally significant domain. Travel planning, for them, is a personal and relational act that cannot be outsourced to impersonal systems. These travelers rely heavily on traditional sources, such as family, friends, or community networks, whom they see as more trustworthy and culturally attuned. Participant 6 explained:

Even if it gives good advice, I won't use it. I'd rather talk to someone who's been there or ask around. It feels wrong to rely on an app for something so personal.

Many in this group felt that AI lacked sensitivity to context, failed to take into account individual needs, or promoted irrelevant or inappropriate suggestions. Several expressed unease with AI "making choices for them," framing it as a threat to autonomy. As participant 15 put it:

...it doesn't know who I am or what matters to me, it just gives the same advice to everyone. ...to be honest that's not how I want to plan my trip.

4.3.2 | Postponers

Postponers represent a more ambivalent stance. These travelers are not fundamentally opposed to AI-generated advice but remain cautious and hesitant. Their resistance takes the form of delay rather than outright rejection. This group is open to trying AI tools, but only under conditions that reduce uncertainty, such as peer endorsement, observed success, or improved system transparency. Their hesitation often stems from usage-related frustrations or risk perceptions, including concerns over errors, generalizations, or opaque recommendation logic. Some also struggle with breaking long-established habits or feel unsure how to interact effectively with AI systems. As interviewee 8 noted:

I'm not against it, but I'm still not sure how reliable it is. Maybe in the future when I hear more people using it successfully, I'll try it. I still prefer asking friends or using online forums.

Postponers reflect a transitional group, aware of the potential benefits but unwilling to risk disappointment or loss of control. As participant 18 noted:

It sounds helpful, but I don't want to depend on it and then have things go wrong... I need to be sure it actually works before I can trust it... I can not trust it for my trip planning.

4.3.3 | Opinion Leaders

This group demonstrates the most active form of resistance. Unlike rejecters, they do not simply opt out; they critically engage, question, and often oppose AI-driven systems. Their resistance is informed by value and image barriers, reflecting both personal conviction and concern about how AI affects collective practices. These travelers often frame generative AI as foreign, disconnected, or misaligned with their values and local realities.

Their resistance is expressive, ranging from vocal critique to efforts to dissuade others from using AI tools. Participant 15 stated:

These AI platforms don't really get us. They suggest places just because they're popular, not because they actually suit someone from here....honestly I think it feels like they don't see who we are or what matters to us. I've already told my friends not to rely on those apps for planning trips, and I think we should let others know too, it's better not to put too much trust in them.

These individuals often interpret AI as reinforcing dominant logics that fail to recognize alternative knowledge systems or localized travel practices. Their opposition is sometimes linked to broader concerns about surveillance, homogenization, or digital dependency. As participant 12 stated:

What frustrates me is that ChatGPT mostly suggests places that are popular in Western media, tourist spots, Instagram-famous landmarks, and things like that. But it rarely brings up places that matter to us personally or culturally. Even if the information isn't wrong, it feels distant, like someone else deciding what's important. I've told people around me to be careful with it...of course it is just my opinion.

Participant 21 also added:

... It's not just about getting a few things wrong. The bigger issue is that we're putting trust in a system that doesn't really understand us. When AI starts shaping our choices, even in small ways, it can shift how we travel and what we think is important. It feels like we're losing control over what the trip actually means...that's why I've been posting about it in my Telegram groups and on Instagram and Facebook, to get people thinking. Some agree, some don't, but it's a conversation we need to have.

5 | Discussion

While generative AI tools like ChatGPT offer substantial potential to streamline travel planning through automation and personalization (Wong et al. 2023; Saleh 2025), the present study reveals that their adoption remains constrained by a set of interrelated functional, psychological, and socio-cultural barriers. These findings build on, but also challenge, prior research that emphasized the benefits of AI in tourism (e.g., Zhu et al. 2024; Kim et al. 2024) without sufficiently addressing the reasons for user hesitation.

Consistent with previous research on technology resistance (e.g., Huang et al. 2021; Kaur et al. 2020; Talwar et al. 2020; Baklouti and Boukamcha 2024), the study confirms that functional limitations, including usability challenges, limited perceived value,

and risk concerns, are central to travelers' reluctance to adopt AI-generated travel advice. While prior work has emphasized GAI's ability to enhance efficiency and reduce information overload (Gursoy and Cai 2025; Dwivedi et al. 2024; Wong et al. 2023), participants in this study frequently described the opposite: fragmented features, cumbersome query formulation, and the need to consult multiple platforms to verify or act on AI suggestions, which find support in the broader literature on technology resistance (Kaur et al. 2020; Talwar et al. 2020; Baklouti and Boukamcha 2024). The usability barrier was evident in reports of unstable internet access, difficulties in phrasing effective prompts, and AI's inability to support complex planning tasks, such as multi-city itineraries. These findings reaffirm that when a new tool introduces friction or cognitive overload, rather than simplifying user experience, it is unlikely to be adopted, regardless of its novelty or theoretical potential (Venkatesh and Davis 2000; Shi et al. 2021).

The value barrier emerged most clearly in participants' comparisons between ChatGPT and existing platforms like [Booki ng.com](https://www.booking.com), TripAdvisor, or Google Maps. Many described the AI's responses as redundant, generic, or less informative than user-generated content. In line with the Technology Acceptance Model (Kumar et al. 2022), low perceived usefulness and high effort discouraged further engagement. Even when participants acknowledged GAI's convenience in generating basic suggestions, its inability to complete actions, such as bookings or itinerary integration, was seen as a key limitation. A more novel finding is the way participants framed GAI as inefficient, not because it failed to generate content, but because that content still required extensive verification. Users felt they had to cross-check AI suggestions against trusted sources, thereby negating any time saved. This aligns with prior research showing that trust in AI is not binary but fragile, easily eroded by small errors or perceived unreliability (Ali et al. 2023; Huang et al. 2021).

The study also identifies risk barriers, with particular emphasis on misinformation and hallucinations, a term now frequently used to describe instances where generative AI fabricates plausible but false information (Christensen et al. 2025). In tourism, where accuracy about locations, logistics, and timing is essential, even minor inaccuracies can cause significant disruptions. Unlike traditional search engines that allow users to triangulate between sources, ChatGPT does not offer transparent citation or real-time updates, which elevates trust issues (Ali et al. 2023; Kim et al. 2025; Seyfi, Kim, Nazifi, et al. 2025). Participants cited examples of non-existent sites, outdated visa information, and vague restaurant listings, confirming that perceived unreliability is not abstract, but grounded in lived travel risks (Kim et al. 2025).

The study also highlights psychological resistance, particularly among travelers who view trip planning as an expression of expertise or autonomy. In this context, AI adoption was not simply a technical issue but a threat to self-perception. For some, planning was described as a creative or strategic act, closely tied to personal identity. The use of AI was equated with outsourcing a core travel ritual, leading to concerns about the erosion of skill and credibility. This supports prior research on image barriers, where innovations are rejected for conflicting with

users' self-image or social role (Heidenreich and Handrich 2015; Kaur et al. 2020). These findings also expand on the concept of psychological resistance by showing that perceived complexity interacts with image concerns (Huang et al. 2021). When users found ChatGPT difficult to use or ineffective in adapting to their preferences, their frustration was reinforced by a sense of being out of control, undermining their confidence as independent travelers. This reinforces the insight that negative experiences with interface design can reinforce broader attitudinal resistance (Laukkanen 2016).

The study also highlights the importance of traditional barriers. Many participants framed travel planning not merely as a task, but as a social and cultural activity, one that involves family consultation, negotiation, and emotional investment. AI tools, by contrast, were perceived as isolating, transactional, and culturally misaligned. This extends prior research by showing that resistance to AI is not only based on functionality but also on the disruption of socially embedded practices (Kaur et al. 2020). The study found that participants frequently preferred human sources (e.g., friends, family, travel agents, blogs) not just for informational accuracy, but for their emotional authenticity and lived experience. AI-generated content was repeatedly described as impersonal, generic, and disconnected from the subtleties of actual travel experiences. This confirms earlier observations (Kim et al. 2025) but goes further by illustrating that for many users, the act of planning itself is socially meaningful. When AI replaces that process, it is not only perceived as less effective but also as undermining valued rituals of dialogue, debate, and shared decision-making (Carvalho and Ivanov 2024).

A further novel contribution of this study is its development of a resistance typology grounded in empirical data. Building on, but extending, Kleijnen et al. (2009), we identify three main types of resistance: rejecters, postponers, and opinion leaders. These types form a continuum of resistance, ranging from passive disengagement to active, vocal rejection. This aligns with Heidenreich and Handrich (2015), who conceptualize resistance as varying in intensity, emotional involvement, and communicative action. The addition of opinion leaders, who combine rejection with public critique and community influence, adds a new layer to existing resistance literature. Prior research has identified similar figures in consumer innovation contexts (Heidenreich and Spieth 2013), but few studies have examined how this form of expressive resistance functions in tourism. These individuals actively shape narratives about AI, using their social credibility to warn peers, discredit AI-generated content, or promote alternative sources. Their resistance is not only ideological but performative, manifested in acts of rejection that carry social meaning (Talwar et al. 2020). In contrast, postponers exhibit a more tentative resistance. Their hesitancy is shaped by uncertainty, conditional trust, and a reliance on social proof, echoing findings in research on innovation delay (Laukkanen 2016). Many described themselves as "waiting" for signs of broader adoption or demonstrated success before engaging. This position is dynamic, and several postponers reported changing attitudes as exposure increased, suggesting that resistance may be fluid and situational, rather than fixed. The rejecters in this study reaffirm established insights about passive resistance. However, they also introduced a cultural dimension often missing from models developed in mainstream contexts.

Their non-adoption was not only about usability or performance; it was grounded in discomfort with delegating decisions to a system perceived as impersonal, foreign, or out of sync with cultural expectations (Musyaffi et al. 2022; Vichitkraivin and Naenna 2021). This typology highlights the need to understand resistance as more than a barrier to be overcome. In some cases, it may represent a reasoned response to perceived misalignment between users' values and the logics embedded in digital systems. As such, designing for adoption may require not just improving features, but rethinking the cultural legitimacy and emotional resonance of AI in domains like tourism, where planning is deeply tied to identity, trust, and social interaction.

6 | Conclusion and Implications

6.1 | Theoretical Implications

This study advances the literature on technological innovation resistance in tourism by addressing critical gaps in theoretical frameworks explaining user reluctance toward generative AI-powered travel planning tools. First, while IRT has been widely applied in consumer behavior and technology resistance research, its application in tourism, especially in the context of generative AI, remains limited. Existing studies have largely focused on conventional technologies or general digital platforms (Cham et al. 2024; Chen et al. 2022), often overlooking the specific challenges posed by systems like ChatGPT. This study applies IRT to the context of AI-generated travel advice and demonstrates that the five core barriers—usage, value, risk, image, and tradition—remain relevant but take on new, culturally specific forms. These barriers are not static constructs; they are reshaped by local norms, personal identities, and the social meanings attached to travel. Our findings refine IRT by showing how psychological barriers, particularly image and tradition, reflect perceived threats to cultural identity, social roles, and relational trust. These insights challenge assumptions of universal resistance mechanisms and highlight the need for context-sensitive applications of IRT, especially outside mainstream consumer environments (Seyfi, Kim, Nazifi, et al. 2025).

Second, the study introduces a resistance typology, rejecters, postponers, and opinion leaders, that adds a novel behavioral and social layer to IRT. This typology links functional and psychological barriers to specific user strategies and orientations. It highlights how resistance takes shape not only as an individual decision but also as a socially situated process shaped by identity, influence, and engagement. By positioning resistance as a continuum rather than a binary outcome (Ram and Sheth 1989; Heidenreich and Handrich 2015), the study offers a framework for interpreting behavioral variation among non-users of emerging technologies.

Third, the study identifies identity-driven and role-based resistance as novel dimensions within the image barrier (Cham et al. 2024). Many participants described travel planning as a valued social skill, linked to experience, credibility, and group status. Their resistance stemmed not from usability concerns but from fears that AI use would undermine their self-image as capable planners or reduce their social capital in peer networks. This expands IRT's conceptual scope by reframing image

resistance as a symbolic conflict, not merely a reputational concern. It also introduces a new contextual variable: the perceived erosion of authority or autonomy in culturally meaningful decision-making domains. These insights therefore advance IRT by highlighting how image barriers can be rooted in identity threats and social-role disruption, rather than solely in concerns over external perception.

6.2 | Practical Implications

This study offers targeted recommendations for AI developers, tourism service providers, and destination marketing organizations (DMOs) seeking to reduce user resistance to AI-generated travel advice. The findings highlight the importance of aligning AI design and communication strategies with the distinct concerns of different resistance types. For rejecters, AI tools should avoid fully replacing human involvement. Hybrid models that blend algorithmic suggestions with human advisors can preserve the social and cultural value attached to travel planning. Offering optional, not default, AI assistance can give users a sense of control. Interfaces should also signal cultural sensitivity (e.g., through localized examples, language, and design aesthetics) that reflect regional norms. These elements can help reduce image barriers by making AI appear less foreign and more socially aligned. For postponers, whose resistance is rooted in functional concerns, particularly risk and value, developers should prioritize transparency and gradual trust-building. Clear onboarding processes that explain how AI recommendations are generated, verified, and updated in real time can reduce uncertainty. Systems should include accuracy indicators, source attributions, and user testimonials to signal reliability. Peer-driven content, such as curated itineraries or ratings from similar traveler profiles, can also enhance perceived credibility. Postponers may benefit from sandbox environments or trial features that allow them to explore AI outputs without commitment, reducing the risk of failure or disappointment.

For opinion leaders, who often resist AI for ideological or normative reasons, the response must go beyond usability fixes. Platforms should engage these users through participatory design processes that incorporate their perspectives and feedback into system development. Collaborating with respected community figures, such as local travel bloggers or influencers, to co-create culturally resonant content may also help reduce skepticism. These users are often vocal and influential; addressing their concerns directly can shift public discourse and reshape perceptions more broadly. In addition, reducing perceived risk requires not only technical accuracy but also clear data policies, user consent mechanisms, and visible privacy controls. This is especially important for rejecters and postponers who fear surveillance or data misuse. Interfaces should communicate what data is collected, how it is used, and how users can manage or delete it. To address image barriers, AI systems must do more than function well; they must be seen as socially acceptable. Framing AI as a travel assistant that supports, rather than replaces, human agency can help reduce symbolic resistance. Messaging strategies should emphasize the enhancement of user autonomy and planning skills, rather than efficiency alone. Finally, DMOs can implement AI-driven tools, such as culturally adapted chatbots, on official platforms to provide

location-specific, trustworthy guidance. These tools should prioritize accuracy, align with local travel values, and include interactive feedback features to adjust content dynamically.

6.3 | Limitations and Directions for Future Research

This study offers new insights into traveler resistance to generative AI in trip planning, but several limitations should be noted. First, the research draws on qualitative data from a single developing country, which limits the generalizability of the findings. Cultural and economic factors may shape resistance differently in other contexts (Musyaffi et al. 2022). Future research could adopt comparative or cross-cultural designs to explore how resistance varies across regions and travel markets. Second, the study focuses on experienced outbound travelers. This group was selected because they are more likely to have encountered AI tools during complex planning processes and can reflect on these interactions in detail. However, this focus excludes occasional travelers and those with limited digital fluency groups—that may exhibit different resistance patterns. We acknowledge this limitation and suggest that future studies include a broader range of user profiles, particularly first-time travelers, older adults, and individuals with low digital confidence. Third, this study examines resistance at a specific moment in time. As AI systems evolve, user perceptions may shift. Longitudinal studies are needed to track how resistance changes with improvements in functionality, accuracy, and personalization. Finally, while this study highlights psychological and functional barriers, it focuses on active forms of resistance. Future research could explore passive resistance, including indifference or avoidance, to better understand the full range of non-adoption behaviors.
